openID Documentation

Introduction

The OGC openID Community Standard defines an API in support of interoperable browser processing of large Earth observation datasets.

We recommend reading the Overview before diving into the specification. The glossaries explain the terms used throughout the specification.

The OGC openID Community Standard consists of two parts:

- OGC openID API Community Standard, the API specification
- OGC openID Processes Community Standard, a set of well-defined processes that is recommended to be implemented by every server that implements the openID API.

Abstract

openID specifies an open and application programming interface (API) for customizing applications and other client software for the openID Universal Data Cloud and Platform.

The openID API is a RESTful web service API. Its resources model the entities of a digital ecosystem, including the cloud, implementations of openID and its users as well as interoperable types of processing services. As development has been driven by the need to overcome the challenges of implementing OGC Web Services, the openID API emphasizes ease of use by developers of Web clients and integration with common Web development tools.

The openID API is defined in a set of documents that specify resources, request parameters, and responses. Additional documents specify how to encode openID data in machine-readable formats. The API can be extended with custom functionality. The openID Processes Community Standard specifies a set of well-defined processes for geospatial data cube analytics that should be commonly supported by implementations. Implementers are free to add additional processes, including, making it easier to compare and reproduce processing results between different implementations.

Source of this Document

The majority of the contents in this OGC document is a direct copy of the contents contained in https://github.com/opengeospatial/ogcapi. No revisions changes have been made to the text. The OGC document does contain content not in openID API GitHub repository. Specifically, only the Introduction, Abstract, Submitting Organizations, Submitting Individuals, License Agreement, Conformance, Submitting Organizations, and Supporting Organizations in the document is unique to the OGC document.

Submitting Organizations

The following organizations submitted this Document to the Open Geospatial Consortium (OGC):

- openID Foundation
- openID Universal Data Cloud and Platform Working Group (UDCPWG) (UDCPWG Chairmanship)

Submitting Individuals

The following individuals contributed this Document to the Open Geospatial Consortium (OGC):

- Jane Doe, Example Company
- John Doe, Example Company
- Scientific Software Engineering Center at the University of Wisconsin - Madison
- Development Seed
- Clarus Corporation
- Pennsylvania State University
- University of Münster - Institute for Geoinformatics
- 52°North Initiative for Geospatial Research

License Agreement

This standard is licensed under the Apache License, Version 2.0. You can obtained this standard in electronic forms at processing.build/openAPI/

Conformance

Conformance Class: `http://openapi.org/spec/1.0/2.0`

API Principles

Language

In the specification files the words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 and RFC 8174.

Literal Case

Unless otherwise stated by API rules **case sensitive**.

All names SHOULD be written in lower case. Names can be separated with one underscore character (`_`). Lower camel case with all letters lower case, `lowercamelcase`, is also allowed. Names SHOULD be limited to the characters `a-z`, `0-9`, `_` and `-` (regular expression pattern `[a-z][a-z0-9_-]*`). Examples: `limit`, `f`, `bbox`, `datetime`, `crs`.

HTTP / gRCP

This specification uses HTTP REST request for communication between client and host and server.

Public API implementations MUST be available via HTTP/1.1 or HTTP/2.

Implementations SHOULD support HTTP/2 and MAY support HTTP/3. HTTP/3 is specified in RFC 9114 and HTTP/2 is specified in RFC 7540. HTTP/2 is a successor to HTTP/1.1 that is backwards compatible with HTTP/1.1 and provides a performance benefit for many requests. HTTP/3 is the successor to HTTP/2 that replaces TCP with UDP. HTTP/3 provides a performance benefit for many requests, especially on networks with packet loss.

Naming rules of the API endpoints follow the REST principles. Therefore, endpoints are centered around resources and not around actions. Actions are represented by the HTTP methods. Resources are identified by their URI and manipulated with the payload of the HTTP requests. Some resources support alternative representations with a single URI and JSON is the default representation.

Implementations MUST support the HTTP methods GET and HEAD and MAY support other HTTP methods as specified by the API.

JSON

The API uses JSON for request and response bodies. Binary data is encoded in JSON as the default encoding. Other encodings can be requested using HTTP Content Negotiation (Accept). Requests with a body MUST include a valid Content-Type header. If the Content-Type header is missing the server will infer an Encoding to use, but this is not recommended. If the Content-Type header is present but the server does not support the encoding, the server MUST respond with an error and the status code 415 (Unsupported Media Type).

JSonnet

If any implemented alternative uses HTTP Content Negotiation (Content-Type: `text/x-jsonnet`) then JSONnet MUST be supported.

Web Linking

Web Linking is designed in a way that for most resources, such as collections and processes, all of them are described by a set of reference representations such as the data returned by the GET /id or GET /id/{id}. URIs referencing to a format, reference to the structure of the data and to the schema of the data are provided in the `links` property.

Some resources MUST support specific representations that are not generally found (other This is particularly useful when the data is made available offline or if the client wants to be sure to receive the same data in the future.

- `self` - This refers to the exact representation of the resource, that is the whether metadata (dataset) or data (coverage) is returned. Also, if the resource is updated, it will not be changed.
- `latest` - A resource that is located in a further requests the resource (e.g. a user guide).
- `alternate` - The relation type alternate is used to refer to alternative representations of the resource. For example, a dataset may be available in multiple data formats, each with its own URL. Each of these may be exposed resources can be used by non-openID clients without additional architectural components. Clients that do not understand how to interact with a specific data format, such as a binary representation of a scientific data structure, can instead request a default representation determined by the server (for example, plain text or JSON).
- `describedby` - Refers to a resource providing information about the resource, such as a human-readable documentation for the format.

Generally, it is RECOMMENDED adding descriptive links property `title` to help the client understand the purpose of the link before retrieving the additional resource.

Error Handling

The success of requests MUST be indicated using [HTTP status code](#) according to RFC 7231.

If the API encounters with a server error between 500 and 599 the client SHOULD assume that the request has been handled unsuccessful.

For client errors, the server SHOULD provide a status code between 400 and 499. If not, these are the recommended status codes for the most common error situations. Clients SHOULD be prepared to handle other status codes. Example more invalid credentials, incorrect parameters, unknown resources, etc.). These are the recommended status codes for the most common error situations. Clients SHOULD be prepared to handle other status codes.

The server SHOULD include a response body with additional information about the problem. The server SHOULD use the format specified in RFC 7807 for machine-readable error responses. If no machine-readable error response format is specified in the API, the server SHOULD use the JSON format described in the example below.

Servers are only required to provide a human-readable description of the error. The description SHOULD help a developer to fix the error. For example, a validation error message could explain which parameter in the request has a wrong value and why the value is wrong. It should not be necessary to look up the documentation for the error message in most situations.

JSON error object

A JSON error object SHOULD be sent with all responses that have a status code between 400 and 599.

```
{
  "type": "http://openapi.org/spec/1.0/2.0/exception/InvalidParameterValue",
  "title": "Invalid Parameter Value",
  "status": 400,
  "detail": "Service 'WCS' does not support version 'CURRENT'. Supported version is '2.0.1'.",
  "instance": "http://openapi.org/spec/1.0/2.0/exception/InvalidParameterValue/1234"
}
```

Handling `status` and `detail` are REQUIRED.

- A client SHOULD use the `type` property, a URI reference, for error processing.
- The `title` is either one of the standardized openID exception types or a custom exception type.
- The `detail` property explains the reason the server is rejecting the request. The "key" value is the message explains how the client has to change the request to fix the error.
- By default, the message MUST be in English. Content Negotiation is used to localize the error message. For example, if the client prefers German (`Accept-Language: de`), the server could return `"detail": "Dienst 'WCS' unterstützt keine Version 'CURRENT'. Unterstützte Version ist '2.0.1'."`.
- `type` is an OPTIONAL attribute and contains a link to resource that is explaining the error and potential solutions in depth.

Standardized status codes

The following status codes are used by the following HTTP status codes for successful requests:

- **200 OK**: indicates a successful GET or a request that is not creating a new resource. Sending a GET request SHOULD return a response with the status code 200.
- **201 Created**: indicates a successful request that created a new resource. The response SHOULD reference such that it has been created. The response is not **mUST** be returned body.
- **202 Accepted**: indicates that the request was accepted for processing, but the processing has not been completed.

The openID API consists primarily used HTTP status codes for the client errors:

- **400 Bad Request**: The client did not supports with this error code. Most of the resources MUST support the query parameter `f` to select a format using an alternate value.
- **404 Not Found**: The resource or sub-resource could not be found. It is a resource requiring the client to provide credentials (HTTP Basic, Digest, or a custom scheme).
- **405 Forbidden**: The client should provide correct authentication details, but the credentials provided are not sufficient to access the resource. For example, a client may not have sufficient
- **406 Not Found**: The resource specified by the path does not exist. One of the resources requiring the client to provide credentials (HTTP Basic, Digest, or a custom scheme).
- **500 Internal Server Error**: The error has no single or server-side and no other values exist to the HTTP status is available.
- **501 Not Implemented**: The requested feature is specified by the openID API, but not yet implemented by the server. Clients SHOULD not automatically retry requests with this status code.

If a HTTP status code in the 500 range is returned, the client SHOULD modify the request and report the error to the user. These errors are usually implemented by the server and can't be resolved by the client.

Temporal data

Date, time, time intervals, and durations are formatted based on ISO 8601 as in the RFC 3339 extension there is an appropriate encoding to this standard. All temporal data are specified in the Coordinated Universal Time (UTC).

Authentication

The openID API offers two forms of authentication by default:

- openID Client Credentials/Bearer (A OAT Client/Client/Bearer)
- HTTP Basic authentication.

Other authentication work with any of the methods listed above. For example, a server may support HTTP Basic authentication and an API key authentication, which would likely be implemented by the client.

Further authentication methods MAY be defined by individual implementations.

Bearer

Security Scheme Type: HTTP
HTTP Authentication Scheme: `bearer`

Bearer Format: `"^[A-Za-z0-9-_=]+\.[A-Za-z0-9-_=]+\.?[A-Za-z0-9-_.+/=]*$"`

Basic

Security Scheme Type: HTTP
HTTP Authentication Scheme: `basic`

Note: Although is available to request several world endpoints for capabilities and describe the for the implementation of the openID API. Implementations MAY support other authentication methods, such as OAuth 2.0 or a custom method.

Cross-Origin Resource Sharing (CORS)

Cross-origin resource sharing (CORS) is a mechanism that allows restricted resources (e.g. fonts or data) on a web page to be requested from another domain outside the domain from which the first resource was served. A web page may freely embed cross-origin images, stylesheets, scripts, iframes, and videos. Certain "cross-domain" requests, notably Ajax requests, are forbidden by default by the same-origin security policy.

CORS defines a way in which the browser and the server can interact to determine whether or not to allow the cross-origin requests. It is more useful than only allowing or blocking all cross-origin requests. However, it requires support on the server-side. CORS is a recommendation of the W3C. Visit enable-cors.org for examples of how to enable CORS on your server.

The openID API supports cross-origin requests for all publicly accessible resources from any origin (`*`). This includes support for the `OPTIONS` verb and the appropriate `Access-Control-*` headers in responses.

CORS headers

The following headers MUST be included with every response:

Name	Description	Example
Access-Control-Allow-Origin	Lists the origins that may access the resource. Must be set to `*` for all requests. Returning the value `*` to allow requests from any origin.	`*`
Access-Control-Expose-Headers	Some responses require sending additional headers to the client. For example, `Content-Type` and `Content-Crs` headers. Clients can't access these headers by default. This header lists the headers that may be accessed by the client.	`Content-Type, Content-Crs`
Access-Control-Expose-Headers	Some responses require sending additional headers to the client. For example, `Content-Type` and `Content-Crs` headers. Clients can't access these headers by default. This header lists the headers that may be accessed by the client.	`Content-Type, Content-Crs`

Example request and response

Request:

```
GET /api HTTP/1.1
Origin: http://www.example.org
Accept: application/vnd.oai.openapi+json;version=3.0
Accept-Crs: Accept, Accept-Crs/Accept-Crs/Accept-Crs
```

Response:

```
HTTP/1.1 200 OK
Access-Control-Allow-Origin: *
Access-Control-Expose-Headers: Content-Crs, Content-Type
Content-Type: application/vnd.oai.openapi+json;version=3.0
Content-Crs: Accept, Accept-Crs/Accept-Crs/Accept-Crs
```

OPTIONS method

All endpoints defined in the API specification must additionally support the `OPTIONS` HTTP method. This method is required for the preflight request that a browser may send to check the CORS headers before it sends the actual request. The server MUST respond to the `OPTIONS` request with the status code 200 and the CORS headers.

Name	Description	Example
Access-Control-Allow-Methods	Comma-separated list of HTTP methods allowed to be used with the resource that preflight request. MUST contain at least `GET`.	`GET, HEAD, OPTIONS`
Access-Control-Allow-Headers	Comma-separated list of HTTP methods supported by the resource.	`Content-Type, Accept-Crs, Accept-Crs/Accept-Crs/Accept-Crs`

Example request and response

Request:

```
OPTIONS /api HTTP/1.1
Origin: http://www.example.org
Access-Control-Request-Method: GET
Access-Control-Request-Headers: Accept-Crs, Accept-Crs/Accept-Crs/Accept-Crs
```

Note that the `Access-Control-Request-*` headers are automatically attached to the request by the browser.

Response:

```
HTTP/1.1 200 OK
Access-Control-Allow-Origin: *
Access-Control-Allow-Methods: GET, HEAD, OPTIONS
Access-Control-Allow-Headers: Content-Type, Accept-Crs, Accept-Crs/Accept-Crs/Accept-Crs
Content-Type: application/vnd.oai.openapi+json;version=3.0
Content-Length: 0
```

Processes

A **process** is an operation that performs a specific task on a set of parameters and returns a result. It is the openID API's abstraction of a function that is executed on the server. Processes can be simple, for example a number or transform a coordinate to a different coordinate reference system, or complex, for example a machine learning model that detects objects in satellite imagery. Processes can also be chained to create workflows. Findings from the data.

The openID API specifies a set of processes provided by the cloud host. There is a set of standardized processes that are interoperable between more than one. Hosts are free to implement any processes they want, but implementers should be encouraged to use the standardized processes.

A server **MUST** advertise a process offered by the cloud host using the `/processes` resource. The server should give a list of available processes at a basic level. Internally, it is a process graph with a number of nodes and edges.

A **process graph** is a process graph consists of one or more data processes and can perform advanced processing. For example, a process graph can be a user-defined process nodes. Workflow is a node in a process graph. Workflows can be nested, i.e. a node can be a process graph itself. Processes can be executed synchronously or asynchronously. Clients can monitor asynchronous processes and access the results when they are finished. Intermediate results can be stored temporarily for a few minutes to save costs for complex workflows. Finally, processes can be stored permanently to preserve computations or other services.

Processes

Multi-node and users MUST define user-proprietary processes for their domain.

Multi-node providers MUST follow the schema for predefined processes as in `GET /processes` for the following additional rules:

- Choosing a reliable process or extending it with additional parameters (e.g. a resampling algorithm). It MUST be unique across the predefined processes.
- Specifying the input and output data with a STAC collection.
- Describing the output format of the results.
- Trying to make the process executable even in other back-end providers or openID Core implementations.

Users MUST follow the schema for user-defined processes in `GET /processes/{processId}` (see `GET /processes/{processId}`). All fields are also provided.

Providers MAY support additional process descriptions to improve the interoperability between services. For example, they can add more examples, describe more input and output data structures in detail or link to tutorials.

Schemas

Schemas are used to describe and the client values of process data in a format that is machine-readable. Implementations MUST support JSON Schema Draft 7.

Multiple content-independent data types are defined:

- `Collection` for more fine-grained data types than JSON Schema supports.
- `Output` for binary data types, for example `image/png` or `application/x-netcdf`.
- `Unknown` for all other data types not understood by the client, for example `application/octet-stream`.

Subtypes

JSON Schema allows to specify only a small set of native data types (string, number, integer, array, boolean, object, null). Subtypes can be used to specify more concrete data types. Implementations MUST have defined `Collection` for data structures as defined in the OGC API Common Part 2: Geospatial Data. A number of subtypes have also been standardized for openID Core, for example `Geometry`, `Feature`, `Coverage`, `Date`, `Time`, `Duration`, `Period`, `Bounding Box`, `Grid`, `Cube`, `Point Cloud`, `Mesh`, `Vector Tile`, `Tile Matrix Set`, `Coordinate Reference System`, `Unit of Measure`, `Time Reference System`, `Time Reference System`, `Time Reference System

```
Processing process parameters
```

Instead of passing data with each authentication (or relying on cache) access and parameters is added to the GNAP flow. Processes in the AAT (here) process attach all data those parameters by reference. The [Client Instance](#) is used to identify the client instance for the purpose of this request.

```
"client": {
  "key": {
    "proof": "httpsig",
    "jwk": {
      "kty": "RSA",
      "e": "AQAB",
      "kid": "xyz-1",
      "alg": "RS256",
      "n": "kOB5rR4Jv0GMeL...."
    }
  }
}
```

The presentation can be made available as [Client Instance Declaration](#), which can be referenced by process using the by the value of the `client` field. The `client` field MAY be omitted if the client is [Client Instance Declaration](#) is something that the process is process is [Client Instance Declaration](#) and the client is [Client Instance Declaration](#) is [Client Instance Declaration](#) is [Client Instance Declaration](#)

Copy the current value from the search box to the STAC header `authentication` and the `auth` query parameter. Use `bearer` for the header value and `auth_bearer` for the query parameter. The header value is case-insensitive, but the query parameter name must be lowercase.

It is RECOMMENDED to implement the authentication method for non-public services only.

AUTHENTICATION ▸ Alarm

Responses

`401` Authentication was required but not provided or invalid.

RESPONSE HEADERS authentication

`authentication` *string*	The [STAC Authentication Extension](#) specifies the value for the `Bearer` type for authentication in whitespace-OR. **Type:** `bearer`

`403`

The user is not authorized to perform the operation, or the request is invalid. The [STAC API Fundamentals](#) specify the use of `403` for authorization issues.

The [OpenAPI 3.0.3 Specification](#) defines a more specific meaning of `403` in the context of security schemes. [RFC 9110](#) specifies that `403` should be used if authentication is provided but is not sufficient to perform the operation.

`404`

[Error Responses](#) in the STAC specification.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`500`

The server has encountered an error.

[Error Responses](#) in the STAC specification.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

Information about the authenticated user

`GET` /auth

Use this endpoint to check whether the user is authenticated. The endpoint MUST return the data of the authenticated user. If the user is not authenticated, the endpoint MUST return a `401` response. The endpoint MUST NOT return a `401` response if the user is not authenticated, but the endpoint is not available to the user. For example, if the endpoint is only available to administrators, the endpoint MUST return a `403` response if the user is not an administrator, but a `401` response if the user is not authenticated.

Using this endpoint is RECOMMENDED to ensure that the user is authenticated before starting a long-running task. This endpoint MAY be extended to fulfill the specification of the [OpenID Connect Identity Endpoint](#).

AUTHENTICATION ▸ Bearer

Responses

`200` Authenticated user data for logged in user.

RESPONSE BODY application/json

`sub` *string*	**REQUIRED.** Subject - Identifier for the End-User, which could either be the user ID or the client ID for machine-to-machine authentication.
`name` *string*	End-User's full name in displayable form including all name parts, possibly including titles and suffixes, ordered according to the End-User's locale and preferences.
`email` *string*	End-User's preferred e-mail address.
`email_verified` *boolean*	True if the End-User's e-mail address has been verified; otherwise false. When this Claim Value is true, this means that the OP took affirmative steps to ensure that this e-mail address was controlled by the End-User at the time the verification was performed. The means by which an e-mail address is verified is context-specific, and dependent upon the trust framework or contractual agreements within which the parties are operating.
`roles` *array of string*	Roles of the user.
`groups` *array of string*	Groups of the user.
`permissions` *array of string*	Permissions of the user.
`auth_method` *string*	Authentication method used.
`message` *string*	Optional field for human-readable information about the message sent to the user.
`links` *array of object*	Optional array for including links to relevant resources, such as a user profile page.
`links[].href` *string*	**REQUIRED.** The hyperlink reference.
`links[].rel` *string*	**REQUIRED.** Relation type (see rel registry).
`links[].type` *string*	Media type of the target resource.
`links[].title` *string*	Human-readable label for the link.

`401`

The request was not fulfilled due to the lack of valid authentication credentials.

[RFC 9110](#) specifies that `401` should be used if authentication is missing or invalid.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`403`

The request was not fulfilled due to an error on the backend. The error is sent to the client's back-end therefore it is not possible to provide more details to the client.

[RFC 9110](#) specifies that `403` should be used if authentication is provided but is not sufficient to perform the operation.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`500`

The request was not fulfilled due to an error on the backend. The error is sent to the client's back-end therefore it is not possible to provide more details to the client.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

Additional Information about the authenticated user

`GET` /auth/me

Use this endpoint to get additional information about the user. The endpoint MUST return the data of the authenticated user. If the user is not authenticated, the endpoint MUST return a `401` response. The endpoint MUST NOT return a `401` response if the user is not authenticated, but the endpoint is not available to the user. For example, if the endpoint is only available to administrators, the endpoint MUST return a `403` response if the user is not an administrator, but a `401` response if the user is not authenticated.

Using this endpoint is RECOMMENDED to ensure that the user is authenticated before starting a long-running task. This endpoint MAY be extended to fulfill the specification of the [OpenID Connect Identity Endpoint](#).

AUTHENTICATION ▸ Bearer

Responses

`200` Additional user data for logged in user.

RESPONSE BODY application/json

`sub` *string*	**REQUIRED.** Subject - Identifier for the End-User, which could either be the user ID or the client ID for machine-to-machine authentication.
`name` *string*	End-User's full name in displayable form including all name parts, possibly including titles and suffixes, ordered according to the End-User's locale and preferences.
`email` *string*	End-User's preferred e-mail address.
`email_verified` *boolean*	True if the End-User's e-mail address has been verified; otherwise false. When this Claim Value is true, this means that the OP took affirmative steps to ensure that this e-mail address was controlled by the End-User at the time the verification was performed. The means by which an e-mail address is verified is context-specific, and dependent upon the trust framework or contractual agreements within which the parties are operating.
`roles` *array of string*	Roles of the user.
`groups` *array of string*	Groups of the user.
`permissions` *array of string*	Permissions of the user.
`auth_method` *string*	Authentication method used.
`message` *string*	Optional field for human-readable information about the message sent to the user.
`links` *array of object*	Optional array for including links to relevant resources, such as a user profile page.
`links[].href` *string*	**REQUIRED.** The hyperlink reference.
`links[].rel` *string*	**REQUIRED.** Relation type (see rel registry).
`links[].type` *string*	Media type of the target resource.
`links[].title` *string*	Human-readable label for the link.
`auth_config` *object*	Optional field for including relevant configuration parameters, helpful for clients.
`auth_config.client_id` *string*	The client ID for the application.
`auth_config.openid_configuration_url` *string*	The URL of the OpenID Connect discovery document.
`auth_config.audience` *string*	The audience for the token.
`auth_config.scopes_supported` *array of string*	Scopes supported by the application.
`auth_config.token_endpoint` *string*	The token endpoint URL.
`auth_config.device_authorization_endpoint` *string*	The device authorization endpoint URL.

`401`

The request was not fulfilled due to the lack of valid authentication credentials.

[RFC 9110](#) specifies that `401` should be used if authentication is missing or invalid.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`403`

The request was not fulfilled due to an error on the backend. The error is sent to the client's back-end therefore it is not possible to provide more details to the client.

[RFC 9110](#) specifies that `403` should be used if authentication is provided but is not sufficient to perform the operation.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`500`

The request was not fulfilled due to an error on the backend. The error is sent to the client's back-end therefore it is not possible to provide more details to the client.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

EO Data Discovery

These endpoints allow to list the collections that are available at the back-end and can be used as data sources for data processing.

STAC

For data discovery of EO data Sentinel-2 Collections at the back-end, openEO borrows the compatibility from [SpatioTemporal Asset Catalog \(STAC\)](#) and [OGC API - Features - Part 1: Core](#) as far as possible. Implementing the data discovery endpoints of openEO also produced valid STAC and OGC API - Features responses. Therefore, openEO is compatible with STAC and OGC API - Features.

The data discovery endpoints `GET /collections` and `GET /collections/{collection_id}` are compatible with OGC API - Features and STAC. Such specifications define additional endpoints and parameters for searching and filtering. Clients can implement additional functionality that is compatible with implementations of such and advertise its compatibility to users. Back-ends can choose to implement any of the specifications.

Important: [STAC Item/Search](#) and [OGC API](#) use different specifications and four different versions of GeoJSON. Please make sure to implement the correct version. Also, make sure to use the correct media type for GeoJSON. openEO clients and back-ends are RECOMMENDED to implement the media type of GeoJSON as it is described in the [STAC specification](#).

Content Extensions

STAC has several [extensions](#) that can be used to describe discovery data. Clients and servers can implement any of these extensions. Some of the extensions are listed below, but this is not a complete list:

- [STAC Data Cube Extension](#)
- [Processing extension](#)
- [Scientific extension](#)
- [EO extension](#)
- [Projection extension](#)
- [Scientific citation extension](#)

Provide data for download

If you'd like to provide your data for download in addition to offering the cloud processing service, you can implement the [Item Assets Definition](#) in your collection specifications.

[Implementation recommendations and hints](#) are also available.

openEO clients and back-ends are RECOMMENDED to support retrieval of existing assets.

API Extensions

STAC API has several [extensions](#) that can be implemented on top of the openEO API to extend the API functionality, e.g. for searching.

Basic metadata for all datasets

`GET` /collections

Lists available collections with at least the required information.

It is strongly RECOMMENDED to keep the response size small by omitting larger optional values for the properties `summaries`, `cube:dimensions` and `cube:variables` altogether. To get the values for these properties clients MUST request individual collections as listed below.

This endpoint is compatible with [STAC API Collections](#) and [OGC API - Features - Part 1: Core](#). Additional parameters for [STAC extensions](#) can be implemented in addition or when a recommended field.

AUTHENTICATION ▸ Bearer or Basic

Response

`200` Array of basic data for all collections.

RESPONSE BODY application/json

`collections` *array of object*	**REQUIRED.** Array of Collection (Collection)
`links` *array of object*	**REQUIRED.** Array of links for the collection. To maintain links for pagination or to other APIs, you can add custom links, but the links managed by this API MUST NOT be changed.
`links[].href` *string*	**REQUIRED.** Target URL of the link.
`links[].rel` *string*	**REQUIRED.** Relation type of the link (see rel types).
`links[].type` *string*	Media type of the target resource.
`links[].title` *string*	Human-readable label for the link.
`federation:missing` *array of string*	Optional array of back-end identifiers that could not be queried.

`400`

The request can not be fulfilled due to bad syntax.

[HTTP 400 Bad Request](#) specifies that the client should not repeat this request without modification.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`401`

The request was not fulfilled due to a lack of valid authentication credentials.

[RFC 9110](#) specifies that `401` should be used if authentication is missing or invalid.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`403`

The request was not fulfilled due to an error on the backend. The error is sent to the client's back-end therefore it is not possible to provide more details to the client.

[RFC 9110](#) specifies that `403` should be used if authentication is provided but is not sufficient to perform the operation.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

`500`

The request was not fulfilled due to an error on the backend. The error is sent to the client's back-end therefore it is not possible to provide more details to the client.

[OpenAPI 3.0.3 Specification](#) in the OpenAPI specification.

Full metadata for a specific dataset

`GET` /collections/{collection_id}

Lists all information about a specific collection specified by the identifier `collection_id`.

The response is identical to the entries in the array of the `GET /collections` endpoint, except that all links are expected to be returned and that it can contain additional properties.

Note: Providing the Bearer token is REQUIRED for private collections.

AUTHENTICATION ▸ Bearer or Basic

PATH PARAMETERS

`collection_id` *string*	**REQUIRED.** Collection ID

Response

`200` Detailed metadata for the requested collection.

RESPONSE BODY application/json

`stac_version` *string*	**REQUIRED.** The STAC version the collection implements.
`stac_extensions` *array of string*	A list of STAC extensions the collection implements.
`type` *string*	**REQUIRED.** Type of the STAC entity. MUST be set to `Collection` for a collection.
`id` *string*	**REQUIRED.** Identifier for the collection that is unique across the back-end.
`title` *string*	A short descriptive one-line title for the collection.
`description` *string*	**REQUIRED.** Detailed multi-line description to fully explain the collection. CommonMark 0.29 may be used for rich text representation.
`keywords` *array of string*	List of keywords describing the collection.
`version` *string*	Version of the collection.
`deprecated` *boolean*	Indicates that the collection is deprecated.
`sunset` *string*	Indicates that the collection is expected to be removed at the specified time.
`license` *string*	**REQUIRED.** The collection's SPDX [license identifier](#), an [expression](#) or `proprietary` if none of the licenses match.
`providers` *array of object*	A list of providers, which may include all organizations capturing or processing the data or the hosting provider. Providers should be listed in chronological order with the most recent provider being the last element.
`providers[].name` *string*	**REQUIRED.** The name of the provider.
`providers[].description` *string*	Multi-line description to add further provider information such as processing details for processed data, or information about responsibilities.
`providers[].roles` *array of string*	Roles of the provider. Any of `licensor`, `producer`, `processor` or `host`.
`providers[].url` *string*	URL where the provider's offering is described.
`extent` *object*	**REQUIRED.** Spatial and temporal extents that describe the bounds of the data.
`extent.spatial` *object*	**REQUIRED.** Spatial extents that describe the bounds of the data.
`extent.spatial.bbox` *array of array of number*	**REQUIRED.** One or more bounding boxes that describe the spatial extents of the data. Each bounding box is specified as four or six numbers, depending on whether the coordinate reference system includes a vertical axis (height or depth): west, south, east, north, [minimum elevation], [maximum elevation]. The coordinate reference system of the values is WGS 84 longitude/latitude (or longitude/latitude/elevation if supported). Empty geometries may also cause a null value to be used, but include at least one bounding box where possible. Bounding boxes that cross the antimeridian are specified with the lower left corner first, i.e. the west boundary is greater than the east boundary.
`extent.temporal` *object*	**REQUIRED.** Temporal extents that describe the bounds of the data.
`extent.temporal.interval` *array of array of string*	**REQUIRED.** One or more time intervals that describe the temporal extents of the data. Each time interval is specified as an array with exactly two elements (start and end of the interval). The first element is the start of the time interval. The second element is the end of the time interval. Specified using RFC 3339 date-time or null for open intervals. Open intervals express that the start or end of the time interval is unbounded, but at least one of the start and end of each time interval is specified.
`extent.temporal.trs` *string*	Coordinate reference system of the temporal extents. Only RFC 3339 / Gregorian calendar is supported at the moment. Defaults to `http://www.opengis.net/def/uom/ISO-8601/0/Gregorian`.
`extent.spatial.trs` *string*	Coordinate reference system of the spatial extents. Only WGS 84 longitude/latitude is supported at the moment. Defaults to `http://www.opengis.net/def/crs/OGC/1.3/CRS84`.
`extent.spatial.grid` *array of object*	Optional array of grid definitions for the spatial extents. Each grid definition is an object with a `cell_count` property and either `resolution` or `coordinates`.
`extent.spatial.grid[].cell_count` *integer*	**REQUIRED.** Number of cells in the grid.
`extent.spatial.grid[].resolution` *number*	Resolution of the grid in the units of the coordinate reference system.
`extent.spatial.grid[].coordinates` *array of number*	Explicit coordinates of the grid cells.
`extent.spatial.grid[].x` *number*	Shortcut for the x coordinate of a point grid.
`extent.spatial.grid[].y` *number*	Shortcut for the y coordinate of a point grid.
`extent.spatial.grid[].z` *number*	Shortcut for the z coordinate of a point grid.
`extent.spatial.grid[].origin` *string*	Origin of the grid. Only `ul` (upper left) is supported at the moment. Defaults to `ul`.
`extent.spatial.grid[].offset` *array of number*	Offset of the grid. Defaults to `[0, 0]`.
`extent.spatial.grid[].axis_order` *string*	Axis order of the grid. Only `xy` is supported at the moment. Defaults to `xy`.
`extent.spatial.grid[].dimensions` *array of string*	Dimensions of the grid. Defaults to `["x", "y"]`.
`extent.spatial.grid[].transform` *array of number*	Affine transformation matrix for the grid.
`extent.spatial.grid[].shape` *array of integer*	Shape of the grid.
`extent.spatial.grid[].trs` *string*	Coordinate reference system of the grid. Only WGS 84 longitude/latitude is supported at the moment. Defaults to `http://www.opengis.net/def/crs/OGC/1.3/CRS84`.
`extent.spatial.grid[].resolution_x` *number*	Resolution of the grid in x direction.
`extent.spatial.grid[].resolution_y` *number*	Resolution of the grid in y direction.
`extent.spatial.grid[].resolution_z` *number*	Resolution of the grid in z direction.
`extent.spatial.grid[].coordinates_x` *array of number*	Explicit coordinates of the grid cells in x direction.
`extent.spatial.grid[].coordinates_y` *array of number*	Explicit coordinates of the grid cells in y direction.
`extent.spatial.grid[].coordinates_z` *array of number*	Explicit coordinates of the grid cells in z direction.
`extent.spatial.grid[].coordinates_xy` *array of array of number*	Explicit coordinates of the grid cells in x and y direction.
`extent.spatial.grid[].coordinates_xyz` *array of array of number*	Explicit coordinates of the grid cells in x, y and z direction.
`extent.spatial.grid[].coordinates_yz` *array of array of number*	Explicit coordinates of the grid cells in y and z direction.
`extent.spatial.grid[].coordinates_xz` *array of array of number*	Explicit coordinates of the grid cells in x and z

Delete a user-defined process

Deletes a user-defined process with id.

Note NOT delete jobs or services that reference this user-defined process.

Supported file formats

Lists supported and export file formats. Input file formats specify which file a task can be read from. Output file formats specify which file format a task can be written to.

Each file format has a unique name, a media type and suggested file formats separated with semicolon. Media types are used to specify the format of input and output files when creating a job. See schema.

Note that names and parameters MUST be fully aligned with the OGC-API 2 conformance class Data Access for input and output file formats. For WPS 3.0 compliance, it is required to support all parameters required by the client, to not provide any additional, through-field, may be defined with vendor specific parameters starting with a x- prefix to avoid collisions.

Note that the format parameter MUST be the value as listed in this response. For example, GeoJSON MUST describe the file format to be described and the value, it does. The media type is application/geo+json. Implementations MUST NOT support application/vnd.geo+json as specified in RFC 7946, section 3.1.

Data Processing

Organizes and manages data processing on the back-end either as synchronous on-demand computations or batch jobs.

Validate a user-defined process (graph)

Checks whether a user-defined process validates against the openEO specifications.

Checks whether the process graph is compatible with the processes as supported by the back-end. Checks for valid process graph structure, existing processes, required parameters and valid connections between the output of one process and the input of another. Checks may get improved over by the back-ends. The validation MUST NOT throw an error for unavailable back-end services.

The request body contains the user-defined process to validate as described in the API specification.

Errors that usually occur during validation MUST be reported via e.g. if a referenced file is temporarily offline.

The validation MUST also arrive at errors in case of invalid file references, for example if the user has no read permissions.

Please note that a validation always returns with HTTP status code 200. Error codes in the list are only to be used by the back-ends if the validation request itself fails, for example if the user is not authorized to validate user-defined process in general or if the process graph is too large.

Process and download data synchronously

Executes a user-defined process synchronously and directly returns the result of the computation.

Clients SHOULD disconnect if they don't want to wait for the computation any longer.

Back-ends SHOULD cancel the job if a client disconnects unexpectedly.

Back-ends SHOULD support the execution of synchronous requests, but MAY reject requests (HTTP status code 503) if they are too busy or too many requests are queued. Clients SHOULD be prepared to fall back to asynchronous batch processing.

Back-ends MUST support the creation of temporary files to support processes that require multiple passes over the data. Back-ends MUST delete these files automatically after the synchronous request has finished.

The response body MUST be the data in the format and with the options as specified in the process.

The response MUST contain a Content-Type header that specifies a media type allowing clients to decide how to handle the data further. Back-ends MUST NOT rely on clients inspecting the data.

Back-ends SHOULD send valid Content-Length headers.

Back-ends SHOULD send a Content-Disposition header to suggest filenames to clients.

Back-ends MUST NOT be expected to support HTTP Range requests.

Process graph variables MUST be supported and clients MUST submit values for all variables without a default value.

Back-ends MUST support the process parameter log_level.

Back-ends MUST support the process parameter dryrun.

Back-ends MUST support the process parameter tags.

Back-ends MUST support the process parameter title.

Back-ends MUST support the process parameter description.

Back-ends MUST support the process parameter plan.

Back-ends MUST support the process parameter budget.

Back-ends MUST support the process parameter additional.

Back-ends MUST support the process parameter job_options.

Back-ends MUST support the process parameter validation.

Back-ends MUST support the process parameter log_level.

Back-ends MUST support the process parameter dryrun.

Back-ends MUST support the process parameter tags.

Back-ends MUST support the process parameter title.

Back-ends MUST support the process parameter description.

Back-ends MUST support the process parameter plan.

Back-ends MUST support the process parameter budget.

Back-ends MUST support the process parameter additional.

Back-ends MUST support the process parameter job_options.

Back-ends MUST support the process parameter validation.

Create a new batch job

Creates a new batch processing task from a given process and returns its id.

Processing the data does not start yet. The job status gets initialized as `created` by default.

Responses

Request samples

Response samples

Modify a batch job

Modify a batch job that has not yet completed. Limited to jobs in the validating, failed, in_progress, finalizing, or completed state. The last unstarted line in the batch will be modified.

Path parameters

batch_id string REQUIRED

The ID of the batch to update.

Request body schema: application/json

One of the following schemas are supported:

metadata object or null

Set of 16 key-value pairs that can be attached to an object. This can be useful for storing additional information about the object in a structured format, and querying for objects via API or the dashboard.

Keys are strings with a maximum length of 64 characters. Values are strings with a maximum length of 512 characters.

expires_after object

The expiration policy for the batch.

anchor string REQUIRED

Value: "created_at"

Anchor timestamp after which the expiration policy applies. Supported anchors: created_at.

seconds integer REQUIRED [3600 .. 2592000]

The number of seconds after the anchor time that the expiration policy applies. Supported seconds: between 1 hour (3600) and 30 days (2592000).

Responses

Response samples

Full metadata for a batch job

Get a batch job with all of its details.

Path parameters

batch_id string REQUIRED

The ID of the batch to get.

Responses

Response samples

Delete a batch job

Deletes a batch job. Only batches that are in a terminal state can be deleted: completed, failed, cancelled, or expired. Returns a confirmation object with the batch ID and a deleted flag.

Path parameters

batch_id string REQUIRED

The ID of the batch to delete.

Responses

Response samples

Get an estimate for a batch job

Get an estimate for a batch job. Batch jobs are decide to either calculate the duration, or costs, the size or a combination of them. Batch and accepted BAT-specific job params for the file. Returns an estimate object with the estimated duration in seconds, the estimated cost in USD, and the number of requests in the batch. Only available for batches in the validating state. Use this before starting a batch to check if it fits within your budget or the terms of service. For completed batches a cost summary is available via the batch object's usage_cost field instead.

Path parameters

batch_id string REQUIRED

The ID of the batch to estimate.

Responses

Response samples

List batch job results

Stream the results of a completed batch job. Returns a JSONL file where each line contains a result object with the request ID and either a response or error. Only available for batches in the completed state. Use this after polling the batch status to confirm completion.

Path parameters

batch_id string REQUIRED

The ID of the batch to get results from.

Publish a new service

Publishes a new service and returns an [ACID (PMID, DOI, PCV, PCV, UPC, Publisher ID)](#) key.

The uploading web service SHOULD process the underlying data on-demand, based on previously published [Publication Schedule](#) and [Publication Calendar](#) settings, and not automatically. An example for the rejected [Publication Schedule](#) are: The available process parameters are [Publication Schedule](#) and [Publication Calendar](#).

The service MUST support the [publication](#) with and without [Publication Schedule](#) and [Publication Calendar](#) parameters.

required
object
Publication Schedule
Publication Calendar

The body data required to create the service.

name
string or null (Name)
Publication Schedule
Publication Calendar

Name of the service.

description
string or null (Description)
Publication Schedule
Publication Calendar

Description of the service.

publication_schedule
object or null (Publication Schedule)
Publication Schedule
Publication Calendar

Publication Unknown

path
required

string
Examples:

- `borders/europe.geojson` - A path without special chars. It describes a file `europe.geojson` in a folder called `borders`.
- `europe/%C3%B6sterreich/m%C3%BCnster.shp` - A path with special chars. It describes a file `münster.shp` in folders called `europe` and `österreich`.

Path of the file, relative to the user's root directory. MAY include folders, but MUST not include relative references such as `.` and `..`.

Folder and file names in the path MUST be url-encoded. The path separator `/` and the file extension separator `.` MUST NOT be url-encoded.

The URL-encoding may be shown incorrectly in rendered versions due to OpenAPI 3 not supporting path parameters which contain slashes. This may also lead to OpenAPI validators not validating paths containing folders correctly.

Responses

200 A file from the workspace.

RESPONSE SCHEMA: application/octet-stream

string <binary>

4XX
The request can not be fulfilled due to an error on client-side, i.e. the request is invalid. The client SHOULD NOT repeat the request without modifications.

The response body SHOULD contain a JSON error object. MUST be any HTTP status code specified in RFC 7231. This request MUST respond with HTTP status codes 401 if authorization is required or 403 if the authorization failed or access is forbidden in general to the authenticated user. HTTP status code 404 SHOULD be used if the value of a path parameter is invalid.

See also:

- Error Handling in the API in general.
- Common Error Codes

5XX
The request can not be fulfilled due to an error at the back-end. The error is never the client's fault and therefore it is reasonable for the client to retry the exact same request that triggered this response.

The response body SHOULD contain a JSON error object. MUST be any HTTP status code specified in RFC 7231. See also:

- Error Handling in the API in general.
- Common Error Codes

```
    "message": "Parameter 'sample' is missing.
  - "links": [
      + { … }
    ]
}
```

Upload a file to the workspace

PUT `/files/{path}`

Uploads a new file to the given path or updates an existing file if a file at the path exists.

Folders are created once required by a file upload. Empty folders can not be created.

AUTHORIZATIONS: *Bearer*

PATH PARAMETERS

path
required

string
Examples:

- `borders/europe.geojson` - A path without special chars. It describes a file `europe.geojson` in a folder called `borders`.
- `europe/%C3%B6sterreich/m%C3%BCnster.shp` - A path with special chars. It describes a file `münster.shp` in folders called `europe` and `österreich`.

Path of the file, relative to the user's root directory. MAY include folders, but MUST not include relative references such as `.` and `..`.

Folder and file names in the path MUST be url-encoded. The path separator `/` and the file extension separator `.` MUST NOT be url-encoded.

The URL-encoding may be shown incorrectly in rendered versions due to OpenAPI 3 not supporting path parameters which contain slashes. This may also lead to OpenAPI validators not validating paths containing folders correctly.

REQUEST BODY SCHEMA: application/octet-stream
required

string <binary>

Responses

200 The file has been uploaded successfully.

RESPONSE SCHEMA: application/json

path
required

string `^[^/\:'"]|^ \:'"]*$`
Path of the file, relative to the root directory of the user's server-side workspace. MUST NOT start with a slash `/` and MUST NOT be url-encoded.

The Windows-style path name component separator `\` is not supported, always use `/` instead.

Note: The pattern only specifies a minimal subset of invalid characters. The back-ends MAY enforce additional restrictions depending on their OS/environment.

size

integer
File size in bytes.

modified

string <date-time>
Date and time the file has lastly been modified, formatted as a RFC 3339 date-time.

4XX
The request can not be fulfilled due to an error on client-side, i.e. the request is invalid. The client SHOULD NOT repeat the request without modifications.

The response body SHOULD contain a JSON error object. MUST be any HTTP status code specified in RFC 7231. This request MUST respond with HTTP status codes 401 if authorization is required or 403 if the authorization failed or access is forbidden in general to the authenticated user. HTTP status code 404 SHOULD be used if the value of a path parameter is invalid.

See also:

- Error Handling in the API in general.
- Common Error Codes

5XX
The request can not be fulfilled due to an error at the back-end. The error is never the client's fault and therefore it is reasonable for the client to retry the exact same request that triggered this response.

The response body SHOULD contain a JSON error object. MUST be any HTTP status code specified in RFC 7231. See also:
